No questions asked they sent a call tag for the wrong one and sent out the correct one. None of them are hooked up and running. On each mobo there is a sticker with a barcode and a number CN0GM81913740817033Z CN06P791698612B91D9C CN06U2144811129J008C Now as I understand it, the 6 digits after CN supposedly refer to the machine they came from. For example I was able to determine the first one listed above goes to an OptiPlex 755. The other two I find nothing. Any ideas CN means made in China, MX means made in Mexico, KR means Made in Korea. If anyone could help me out it would be greatly appreciated. In the event a late installation may cause problems, you may have to reinstall XP. The links to all reinstall instructions for your system are here. Since you don't have the original CDs you will have to go to the Downloads link above the forum to download the necessary drivers. Follow the prompts until you see the search criteria. Install the chipset first, then the video, then audio. You'll recognize which is which for it has a check mark next to it. You may also login in the Product Support menu and choose Reinstall Guide for detailed instructions. Now all I need is the usb controller driver and my multimedia controller driver. In all, it'll be a lot easier if you replace the case with the mainboard. How many posted that their motherboard did not fail. Not too many I bet. I doubt that the failure rate was high. I also didn't know that hundreds of thousands of the 6U214 were sold. Would love to have your source of information. BTW, I have an ABIT BE7 that hasn't fried yet. They made millions. Easily. Just look at their volumes and even a percentage of that is huge. Oh, and by the way, I've been in this newsgroup for years and yours is the first failed 4550 that I remember reading about. Not saying it doesn't happen, as clearly it does, but it is not a known problem. Personally, I'd bet on a power spike. You must have missed the point of this thread, and of this group. To help people. As for your market research, since you claim that Dell sold millions of one particular model, I'll bet they've sold billions of PCs since they've been in business.

All told, I'll bet there have been hundreds of billions of PCs sold since the beginning of time. We are working every day to make sure our community is one of the best. So my question is. about a year later I think my dad bought me a 512 chip of ram for it so we pulled out a 256 chip and inserted the 512. Then probably another year later he bought me a gig of ram, so in my computer to this day now currently has a 333MHz 1 gig chip and a 512 166MHz Im almost positive it is 166MHz or maybe 133MHz at work right now, going to double check when i get home tonight. Big question is, is all this time my computers memory been running at 166MHz because I had the older chip in it. Also, another question is, I went to Dell.com, used the support for system specs, used my computer tag number, looked at upgrading ram, and its telling me that I can buy 400 MHz FSB for it. Therefore all this time I could be running 400 MHz and I am currently running a 1gig 333 MHz and a 512 166MHz. Any input would be extremely helpful. Or Im not even sure if they have 533 MHz ram. Also, looking even deeper. Thanks, Doug. Reliability then depends on whether the fast RAM is stable running at a lower speed. Intel processors FSB, IIRC, is not directly related to RAMs speed. The FSB speed is used only between the processor and the northbridge chipset. Whats tricky though is that modern memory is DDR which stands for double data rate RAM, and its speeded at twice the speed of your memory clock. There are several DDR flavors, DDR266, DDR333, and DDR400, which operate at 133MHz, 166Mhz, and 200MHz respectively. DDR333 corresponds to PC2700 memory, but the whole shebang is still running at 166Mhz. I think youre confused as to which is the actual memory clock speed and which is the DDR memory spec.

Intel motherboards from that day ran their front side bus at 533 MHz, which, though impressive at the time, has little to do with the memory clock aside from the memory clock divider being very unusual. Their FSB was described as quadpumped, so it ran 4 times faster than the regular bus clock, which on your machine is 133MHz. The memory clock is usually derived from the regular bus clock, but sometimes its synchronized to it. If thats the case with you, then your memory clock is actually running at 133MHz and theres little you can do about it. In other cases though, you can set the memory clock to run differently than the bus clock and that will allow you to run your memory at full spec. If you motherboard can support DDR400 ram, then you could purchase PC3200 ram instead of the PC2700 RAM that you have and run that, though I dont know if youll see any noticeable performance gains. Otherwise, Id interpret your statement as saying that your machine can run its FSB at 400MHz rather than 533MHz. BTW, maximum memory most likely represents the maximum memory allowable per slot. So you cant put in a 2 Gig single stick of PC2700 and expect it to work. So you are saying that my ram isnt actually running at 333 MHz, but something a bit slower. On the ram chip it says 333 MHz, and my computer is capable of 533 MHz. And Dell says I should buy PC3200 Ram nowadays. So if I go buy another 1gig stick of pc3200 400 MHz, my system will still run at 333 MHz because of my other stick of ram. In order to maintain the same speed and power over a long distance, you would need two horses that have more or less the same characteristics. If you have a highlytrained horse and a horse that is old and doesnt have much power, you would have

to go only as fast as the old horse can go, even if the trained horse could do better. I am not 100% sure, but you might be able to overclock the memory to run at a faster speed, but that might affect the stability of the system.

Also check for registered ram or ecc compatibility. Try not to mix different brands, speeds, and sizes although this is not necessarily required and your pc will probably be able to adapt, but with reduced performance sometimes. Also, know how much you need. if you are running win2k and surfing the web, you dont need 2GB, but if you want a vista gaming machine, Id invest in at least that. Try opening the task manager at different times to see how much you use when running different things to get a feel for it. DDR 400 PC 3200 is pretty cheap right now because of the shift to DDR2. If you plan to continue using that computer for at least a little longer, I say invest. And maybe in a year or so I do plan to change to Vista. For the time being Vista is too damn buggy to actually use in my opinion after using it for 5 months. That label which SHOULD be accurate incorporates the speed it runs at. Its a convoluted system, but so long as theyre the same PCxxxx value, then you know they should be running at the same speed. To give you an idea, memory that is actually supposed to run at 333MHz not DDR333, but DDR667, it would be called PC5300. Given the current state of memory and the age of your computer, Im fairly certain that your memory clock is running at either 133MHz or 166MHz, and not 333MHz. That label which SHOULD be accurate incorporates the speed it runs at. Given the current state of memory and the age of your computer, Im fairly certain that your memory clock is running at either 133MHz or 166MHz, and not 333MHz. Dells website says my computers motherboard can actually handle a 533 MHz bus. Ill look up more information on that chip of ram and find out 100% what it is. This system works by counting both leading and trailing pulses thus doubling the effective data rate between CPU and RAM. Page Count 237 The OpenFOAM Foundation. User Guide Author Christopher J.
